

The Macroeconomic Impact of Microeconomic Shocks: Beyond Hulten's Theorem

David Baqaee Emmanuel Farhi

LSE Harvard

May 23, 2017

Macroeconomic Impact of Shocks

- For economy with efficient equilibrium, Hulten (1978):

$$d \log C / d \log A_i = \text{sales}_i / GDP = \lambda_i.$$

- First-order approximation or log-linearization.
- Foundation for Domar aggregation:
 - sales approximate sufficient statistics.
 - details of production structure are irrelevant.
- “Bugbear” for production networks literature:

Macroeconomic Impact of Shocks

- For economy with efficient equilibrium, Hulten (1978):

$$d \log C / d \log A_i = \text{sales}_i / \text{GDP} = \lambda_i.$$

- First-order approximation or log-linearization.
- Foundation for Domar aggregation:
 - sales approximate sufficient statistics.
 - details of production structure are irrelevant.
- “Bugbear” for production networks literature: Walmart and Electricity equally important – to a first order.

What We Do

- Extend Hulten to second order to capture nonlinearities.
- General formula: reduced-form macro-elasticities of substitution.
- Mapping from micro to macro using a general structural model:
 - structural elasticities of substitution.
 - returns to scale.
 - factor market reallocation.
 - network linkages.
- Nonlinearities lead to asymmetric responses of output to shocks.
 - amplification of negative shocks, attenuation of positive shocks.
 - lower mean, negative skewness, excess kurtosis.
- Nonlinearities quantitatively important:
 - $\times 10$ welfare costs of business cycles from 0.05% to 0.6% of GDP.
 - $\times 4$ impact of 70's oil price shocks from -0.7% to -2.4% of GDP.

What We Can Also Do

- Paper focuses on output, not co-movement, but can be characterized with same macro-elasticities.
- Paper does not focus on diversification argument, but characterization of nonlinearities relevant for it.
- Paper abstracts away from RBC channels (elastic labor supply, capital accumulation), dynamics (reallocation), frictions (markups, wedges).
- Tackle in ongoing work.

Agenda

Framework

Structural Model

Macro-Substitution

Networks

Quantitative Examples

Conclusion

General Framework

- Perfectly competitive economy, representative consumer.
- Preferences represented by CRS consumption-bundle metric

$$C = \mathcal{C}(c_1, \dots, c_N),$$

where c_i is consumption of good i .

- Consumer budget constraint

$$\sum_i p_i c_i = \sum_{i=1}^M w_i l_i + \sum_{i=1}^N \pi_i,$$

where p_i , w_i , and π_i are prices, wages, and profits.

General Framework

- Profits earned by the producer of good i :

$$\pi_i = p_i y_i - \sum_{k=1}^M w_k l_{ik} - \sum_{j=1}^N p_j x_{ij}.$$

- Each good i is produced using production function:

$$y_i = A_i F_i(l_{i1}, \dots, l_{iM}, x_{i1}, \dots, x_{iN}),$$

- A_i Hicks-neutral technology (Harrod-neutral as special case).
- x_{ij} intermediate inputs of good j used in the production of good i .
- l_{ik} labor of type k used by i .

Hulten's Theorem

Define $C(A_1, \dots, A_N)$ to be competitive equilibrium aggregate consumption function interpreted as output.

Theorem 1.1 (Hulten)

Let λ_i denote industry i 's sales as a share of output, then

$$\frac{d \log C}{d \log A_i} = \lambda_i.$$

Elasticity of Substitution

Definition 1.2

- For general CRS function $f(A_1, \dots, A_N)$ define Morishima elasticity of substitution:

$$\frac{1}{\rho_{ij}} = -\frac{d \log(MRS_{ij})}{d \log(A_i/A_j)} = -\frac{d \log(f_i/f_j)}{d \log(A_i/A_j)}$$

where $f_i = \partial f / \partial A_i$.

- For output function $C(A_1, \dots, A_N)$, define *macro-elasticity of substitution*:

$$\frac{1}{\rho_{ij}} \equiv -\frac{d \log(MRS_{ij})}{d \log(A_i)} = -\frac{d \log(C_i/C_j)}{d \log(A_i)},$$

where $C_i = \partial C / \partial A_i$.

- Note that $\frac{d \log(\lambda_i/\lambda_j)}{d \log A_i} = \frac{d \log[(C_i A_i)/(C_j A_j)]}{d \log A_i} = \frac{d \log(C_i/C_j)}{d \log A_i} + 1 = 1 - \frac{1}{\rho_{ij}}$.

Input-Output Multiplier

Definition 1.3

Define input-output multiplier

$$\sum_{i=1}^N \frac{d \log C}{d \log A_i} = \sum_{i=1}^N \lambda_i = \xi.$$

- “Macro returns to scale”: $\xi > 1$ implies reproducibility.
- ξ constant if and only if C homogenous of degree ξ .

Extending Hulten: Idiosyncratic Shocks

Theorem

$$\frac{d^2 \log C}{d(\log A_i)^2} = \frac{\lambda_i}{\xi} \sum_{j \neq i} \lambda_j \left(1 - \frac{1}{\rho_{ij}} \right) + \lambda_i \frac{\partial \log \xi}{\partial \log A_i}.$$

- General formula for second-order terms (nonlinearities) in terms of reduced-form macro-elasticities of substitution.
- Sales distribution not sufficient statistic.
- $\rho_{ij} = 1$, ξ constant: knife-edge case where effect disappears.

Extending Hulten: Common Shocks

Proposition 1.4

$$\frac{d^2 \log C}{d \log A_i d \log A_j} = \frac{\lambda_i}{\xi} \sum_{k \neq j} \lambda_k \left(1 - \frac{1}{\rho_{jk}}\right) + \lambda_i \frac{\partial \log \xi}{\partial \log A_j} - \lambda_i \left(1 - \frac{1}{\rho_{ji}}\right) \quad (i \neq j)$$

- Shocks not additive.
- $\rho_{ij} = 1$, ξ constant: knife-edge case where effect disappears.

Welfare Costs of Business Cycles

Proposition 1.5

Let $u : \mathbb{R} \rightarrow \mathbb{R}$ be a CRRA with parameter γ . Suppose TFP A has idiosyncratic shocks with variance s_k^2 . Then the welfare costs of business cycles are given by:

$$\frac{\overline{C}[E(u(C)) - u(\overline{C})]}{u'(\overline{C})} \approx \underbrace{-\frac{1}{2}\gamma \sum_k \lambda_k^2 s_k^2}_{\text{Consumption nonlinearities}} + \underbrace{\frac{\overline{C}}{2} \sum_k \frac{\partial^2 C}{\partial A_k^2} s_k^2}_{\text{Production nonlinearities}},$$

- Nonlinearities in consumption: small cost in Lucas (1987).
- Nonlinearities in production: can be order of magnitude larger.
- Similar results for macro-moments: mean, skewness, kurtosis, etc.

Mapping Micro Parameters to Macro Elasticities

Proposition 1.6

ρ_{ij} and $d \log \xi / d \log A$ can be solved for explicitly as a function of observable expenditure shares and micro elasticities of substitution.

- See paper for explicit characterization of reduced-form macro-elasticities in terms of micro primitives.

Conclusion

Household

- Preferences given by consumption-bundle metric:

$$\frac{C}{\bar{C}} = \left(\sum_k b_k \left(\frac{c_k}{\bar{c}_k} \right)^{\frac{\sigma-1}{\sigma}} \right)^{\frac{\sigma}{\sigma-1}}.$$

- Consumer budget constraint:

$$\sum_k p_k c_k = \sum_k w L_k + \sum_k w_k l_k + \sum_k \pi_k.$$

Firms

- Industry k 's production function given by

$$\frac{y_k}{\bar{y}_k} = A_k \left(a_k \left(\left(\frac{L_k}{\bar{L}_k} \right)^{\beta_k} \left(\frac{l_k}{\bar{l}_k} \right)^{1-\beta_k} \right)^{\frac{\theta_k-1}{\theta_k}} + (1 - a_k) \left(\frac{X_k}{\bar{X}_k} \right)^{\frac{\theta_k-1}{\theta_k}} \right)^{\frac{\theta_k-1}{\theta_k}}$$

- X_k composite intermediate input given by

$$\frac{X_k}{\bar{X}_k} = \left(\sum_l \omega_{kl} x_{lk}^{\frac{\varepsilon_k-1}{\varepsilon_k}} \right)^{\frac{\varepsilon_k-1}{\varepsilon_k}},$$

where x_{kl} intermediate inputs from industry l used by industry k .

- L_k mobile generic labor and l_k fixed specific labor.

Framework

Structural Model

Macro-Substitution

Networks

Quantitative Examples

Conclusion

Substitution and Reallocation

Proposition 2.1

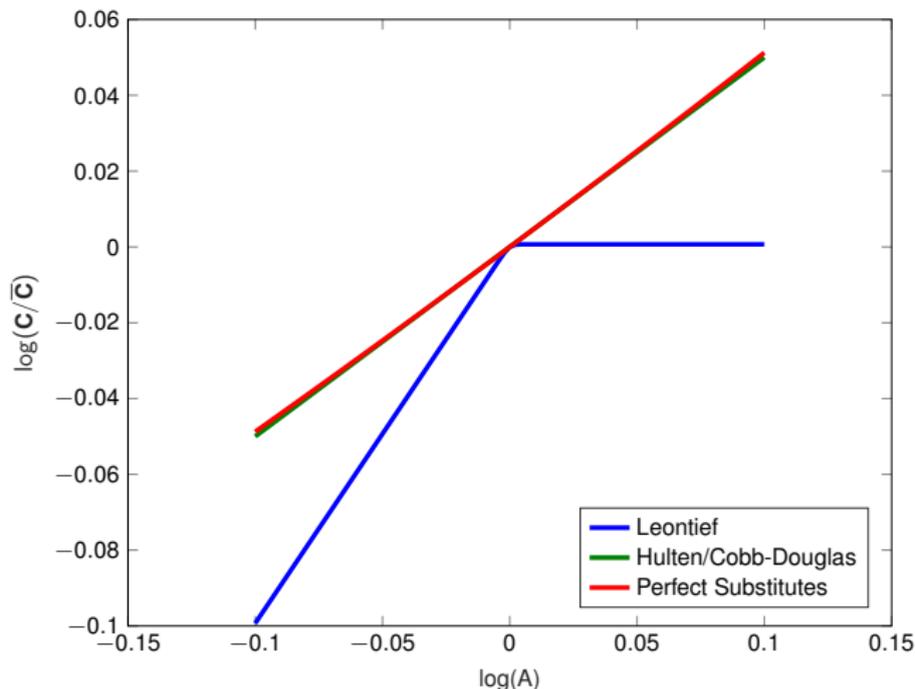

Suppose each good is produced using only labor. Assume uniform labor reallocation/returns to scale $\beta \in [0, 1]$ for every k . Then

$$\rho_{ij} = \frac{\sigma(1 - \beta) + \beta}{\sigma(1 - \beta) + \beta + (1 - \sigma)}, \quad \lambda_i = b_i, \quad \xi = 1, \quad \frac{d \log \xi}{d \log A_i} = 0.$$

- To build intuition, consider polar cases with $\beta = 1$ and $\beta = 0$.

Lesson #1: Micro-Elasticity of Substitution Matters

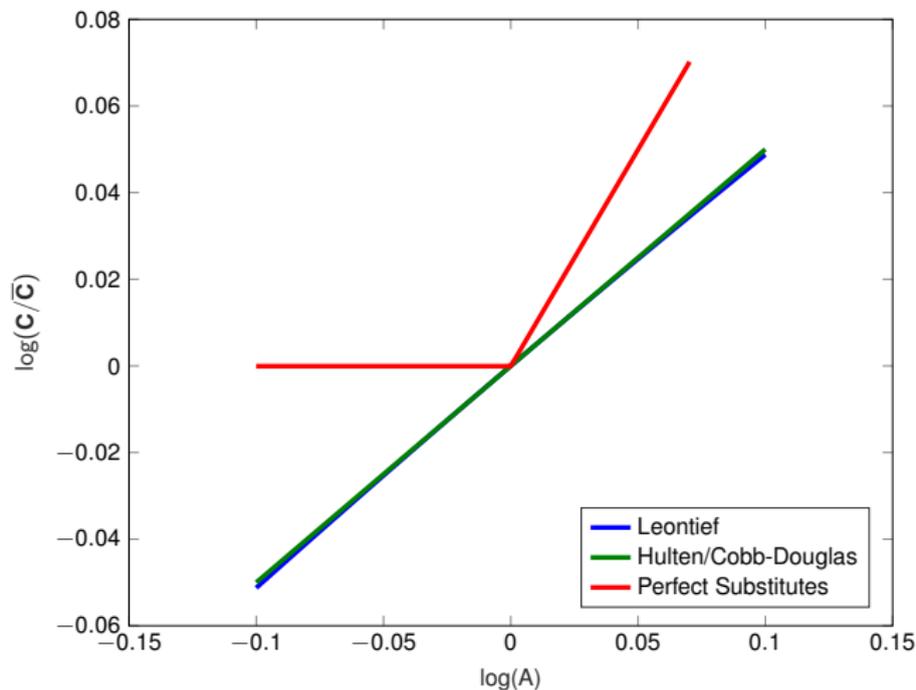

$$\beta = 0 \implies \rho = \sigma.$$

$$\frac{d^2 \log C}{d \log A_i^2} = b_i(1 - b_i) \left(1 - \frac{1}{\sigma}\right).$$

Lesson #2: Reallocation Matters

$$\beta = 1 \implies \rho = \frac{1}{2-\sigma}.$$

$$\frac{d^2 \log C}{d \log A_i^2} = b_i(1 - b_i)(\sigma - 1).$$

Network Irrelevance Result

Proposition 2.2

Let $\sigma = \theta_i = \varepsilon_i$, and consider Harrod-neutral (labor-augmenting) shocks. Then for any arbitrary network

$$\rho_{ij} = \rho, \quad \xi = 1, \quad \frac{d \log \xi}{d \log A_i} = 0,$$

where

$$\rho = \begin{cases} \sigma & \text{if labor cannot be reallocated} \\ \frac{1}{2-\sigma} & \text{if labor can be reallocated} \end{cases}.$$

$$\frac{d^2 \log C}{d \log A_i^2} = \lambda_i(1 - \lambda_i) \left(1 - \frac{1}{\rho}\right).$$

- Extends Hulten network irrelevance to second-order.

Taking Stock

- General formula for second-order nonlinear effects of shocks in terms of macro-elasticities of substitution.
- Reduced-form macro-elasticities of substitution shaped by:
 - structural micro-elasticities of substitution.
 - factor reallocation and returns to scale.
- Network irrelevance if (1) uniform micro-elasticities, and (2) Harrod-neutral (labor-augmenting) shocks.
- Can break network irrelevance with (1) heterogenous production elasticities, and (2) Hicks-neutral (TFP) shocks.

Agenda

Framework

Structural Model

Macro-Substitution

Networks

Quantitative Examples

Conclusion

General Networks

Definition 2.3

The $N \times N$ *input-output* matrix Ω is the the matrix whose ij th element is equal to the steady-state value of

$$\Omega_{ij} = \frac{\rho_j x_{ij}}{\rho_i y_i}.$$

The *Leontief inverse* is

$$\Psi = (I - \Omega)^{-1}.$$

- Ψ_{ij} measures i 's reliance on j .

Networks

Proposition 2.4

Assume $\beta_i = 1$ (CRS, full reallocation), and $\varepsilon_i = \theta_i$ for every i (w.l.o.g.), and Hicks-neutral (TFP) shocks. Then

$$\frac{d^2 \log C}{d \log A_k^2} = (\sigma - 1) \text{Var}_b(\Psi_{(k)}) + \sum_j (\varepsilon_j - 1) \lambda_j \text{Var}_{\Omega^{(j)}}(\Psi_{(k)}).$$

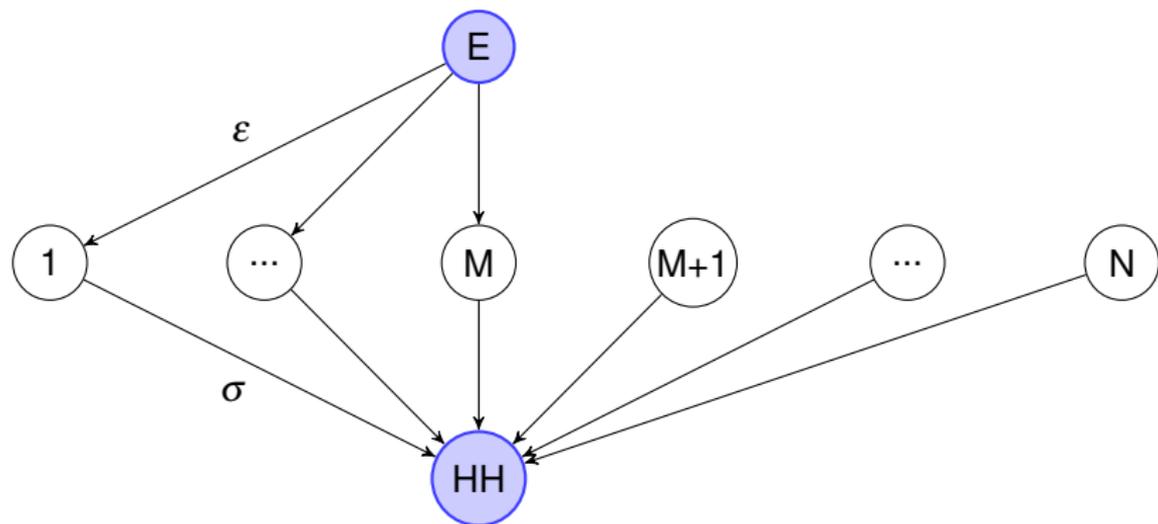

- Weighted variances of Leontief inverse:

$$\text{Var}_b(\Psi_{(k)}) = \sum_i b_i \Psi_{ik}^2 - (\sum_i b_i \Psi_{ik})^2,$$

$$\text{Var}_{\Omega^{(j)}}(\Psi_{(k)}) = \sum_i \Omega_{ji} \Psi_{ik}^2 - (\sum_i \Omega_{ji} \Psi_{ik})^2.$$

- Centrality measure mixing network and elasticities.

Example: Universal Inputs

$$\begin{aligned}\frac{d^2 \log C}{d \log A_E^2} &= (\sigma - 1)\lambda_E \left(\frac{N}{M} - 1 \right) \lambda_E + (\varepsilon - 1)\lambda_E \left(1 - \frac{N}{M}\lambda_E \right), \\ &= \lambda_E(1 - \lambda_E)(\sigma - 1) + (\sigma - \varepsilon)\lambda_E \left(\frac{N}{M}\lambda_E - 1 \right).\end{aligned}$$

Conclusion

Simulation

- Set $\theta_j = \theta = 0.3$, $\varepsilon_i = \varepsilon \approx 0$, and $\sigma = 0.4$ drawing on Atalay (2016), Boehm et al. (2015), Barrot and Sauvagnat (2016), Comin et al. (2015).
- Set $(\sigma, \varepsilon, \theta)$ to match $\sum_i \bar{\lambda}_i \sigma_{\lambda_i} = 0.0197$.
- Impose no-movement in labor for benchmark (Acemoglu et al. (2016), Autor et al. (2016), Notowidigdo (2011)).
- Use the 88-sector US KLEMS annual input-output data from 1960-2005, with sector-level TFP data constructed using Jorgenson et al. (1987) methodology.
- Set sectoral TFP shocks to be $\log \mathcal{N}(-\Sigma_{ii}/2, \Sigma_{ii})$, where Σ_{ii} is sample variance of $\Delta \log TFP$ for industry i .

Simulation Results

	Mean	Standard Deviation	Skewness
GDP Data	–	0.0238	-0.6190
TFP Data	–	0.0147	-0.2888
Benchmark	-0.0057	0.0117	-0.5229
Linear Hulten	0.0000	0.0110	0.0432
$(\theta, \sigma) = (0.1, 0.3)$	-0.0102	0.0138	-1.2864
High Volatility Benchmark	-0.0117	0.0180	-0.8821
High Volatility Hulten	0.0000	0.0155	0.0422

- Welfare costs of business cycles 0.57%, order of magnitude larger than those of 0.05% identified by Lucas (1987).

Histograms

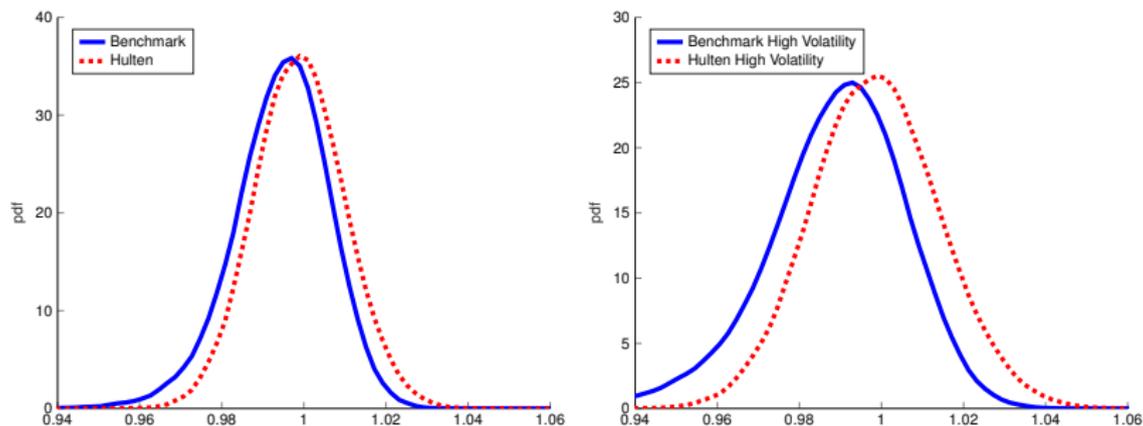

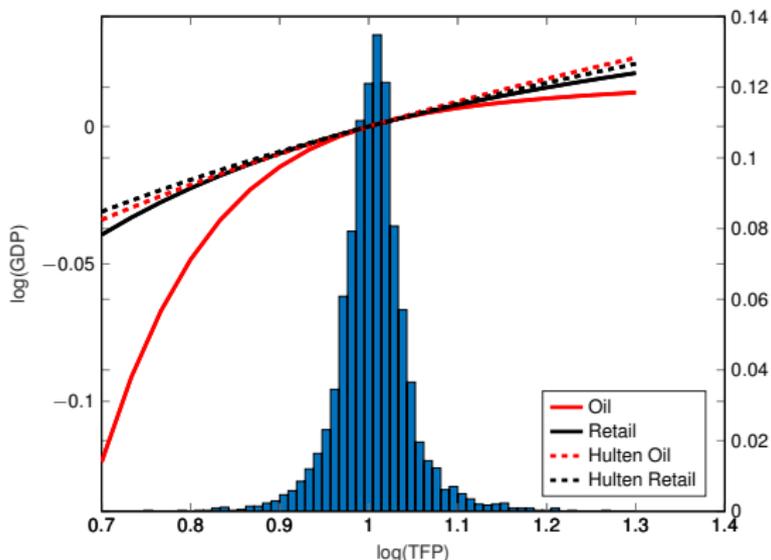

Figure: The left panel shows the distribution of GDP for the benchmark model and log-linearized model. The right panel shows these for shocks whose variance is twice as high.

- Excess kurtosis of 1 in benchmark model, increases with volatility.
- Endogenous and asymmetric fat tails ("rare disasters").

Oil v. Retail

- Intuition: low micro-elasticity of substitution, universal input.
- Consistent with large asymmetric effects of oil shocks (Hamilton, 2003), even without frictions.

Reduced-form Impact of Oil Shocks

Proposition 3.1

Up to the second order in the vector Δ , we have

$$\log(C(A + \Delta)/C(A)) = \frac{1}{2} [\lambda(A + \Delta) + \lambda(A)]' \log(\Delta).$$

Reduced-form Impact of Oil Shocks

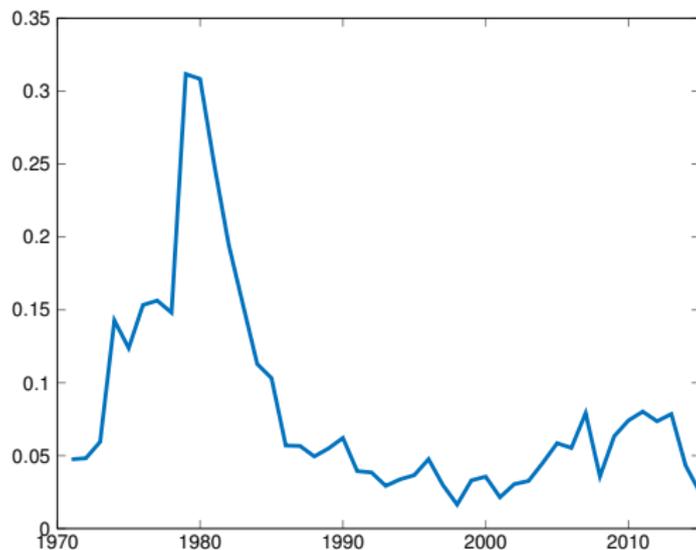

Figure: Global expenditures on crude oil as a fraction of world GDP.

- First-order effect: $5\% \times -13\% = 0.65\%$.
- Second-order effect: $\frac{1}{2}(5\% + 31\%) \times -13\% = 2.34\%$.

Macro-Substitution

Networks

Quantitative Examples

Conclusion

Conclusion

- For empirically relevant cases, nonlinearities missed by first-order approximation are important.
- Second-order terms depend on macro-elasticities of substitution: macro-objects, not identified by micro-variation.
- Micro-elasticities of substitution, factor reallocation, micro-returns to scale, and networks play an important role in shaping these second order terms.
- Ongoing work to allow for frictions (markups/wedges), investigate trade shocks, and RBC channels (elastic labor supply, capital accumulation, dynamics).
