Abstract

Housing prices diverge from construction prices after 1997 in four major countries. Besides, TFP differences between construction and the general economy account for the evolution of construction prices in the U.S. and Germany, but not in the U.K. and Spain.

Keywords: Housing prices, TFP, growth accounting, Cobb-Douglas.

JEL classification: E01, E23, E25, E32.

Resumen

Este documento analiza el papel de las diferencias en crecimiento de la PTF entre el sector de la construcción y la economía en su conjunto para explicar la evolución de los precios reales de la vivienda. Para ello, primero se comparan las sendas de precios de construcción y vivienda en Estados Unidos, Reino Unido, Alemania y España. Se encuentra que, si bien ambos precios siguen tendencias similares antes de 1997, a partir de esa fecha divergen en todos los países. En segundo lugar, se realiza un ejercicio de contabilidad del crecimiento para calcular la contribución de la PTF relativa sobre el precio real de la construcción. Los resultados indican que las diferencias en PTF explican en su mayor parte la evolución de los precios de construcción en Estados Unidos y Alemania, mientras que en Reino Unido y España estos parecen haber sido el resultado de la evolución de los salarios y los retornos al capital.

Palabras claves: Precios de la vivienda, PTF, contabilidad del crecimiento, Cobb-Douglas.

Códigos JEL: E01, E23, E25, E32.

1 Introduction

We investigate the role of differences in TFP growth between the construction sector and the general economy in the evolution of real housing prices in four major countries. We first compare housing prices with construction prices in the U.S., the U.K., Spain and Germany. The first three countries experienced major housing prices booms in the first decade of the 21st Century whereas housing prices in Germany have been roughly stable. We find that housing prices closely follow construction prices during the pre-1997 period while they diverge afterwards in all countries, although to a different extent. Only in the U.S. the two prices are back to a common level in 2007.

Secondly, we use a growth-accounting framework (Solow, 1957, and Jorgenson, Gollop and Fraumeni, 1987) and its dual approach (Oulton, 2007) to assess the contribution of the TFP growth differential between the construction sector and the general economy on construction prices.¹ If TFP grows more slowly in the construction sector than in the overall economy, then the relative price of construction goes up as a particular case of Baumol's "cost disease" (Baumol, 1967). Our results suggest that the surge in construction prices in the U.S. is the consequence of an increase in relative TFP growth between the general economy and the construction sector, especially since the mid-90s.² Relative TFP also drives construction prices in Germany. However, we find that the rise in construction prices in both the U.K. and Spain is not due to TFP differences but to relative rental prices of labor and capital between the construction sector and the general economy.

2 Housing Prices versus Construction Prices

Figure 1 displays construction and housing prices for the U.S., the U.K., Germany and Spain from 1987 to 2007.³ In the U.S., housing prices track construction prices until 2001. During the "housing boom", from 2002 to 2006, house prices rise faster than construction ones. In 2007, housing prices fall to the same level as construction prices. Overall, construction prices grow around 70% since 1987, a magnitude similar to the increase in housing prices. In the U.K. and in Spain, instead, house prices more than double in the decade 1997-2007 whereas construction prices only grow around 40%. In Germany, house prices fall more than 10% after 2003 whereas construction prices slightly grew. Thus, construction prices seem to play a pivotal role in the evolution of house prices in the U.S., whereas the relationship between both prices is feebler in the other countries.

3 Growth Accounting Methodology

We assume that production in the construction sector c and in the general economy g at time t , $Y_{i,t}$, follows a Cobb-Douglas function:

$$Y_{i,t} = A_{i,t} K_{i,t}^{\alpha_i} L_{i,t}^{1-\alpha_i}, \quad i = \{c, g\}, \quad (1)$$

¹In contrast with standard growth accounting that requires quantity indices to be implemented, the dual growth accounting requires the use of price indices. Oulton (2007) uses this approach to compute the relative price of equipment to consumption. See also Hsie (2002).

²Iacoviello and Neri (2010) and Khan (2008) find a similar result in the context of dynamic general equilibrium models. For the acceleration of aggregate TFP in the U.S. see Jorgenson and Stiroth (2000).

³The appendix provides a description of the data.

where $K_{i,t}$ and $L_{i,t}$ are, respectively, the sector-wide capital and labor services and $A_{i,t}$ is total factor productivity (TFP). Capital and labor services in the two sectors are not required to be homogenous. Given (1), TFP can be computed using data on sectoral output, capital services and labor services.

With competitive markets, the price of one unit of $Y_{i,t}$ is, in equilibrium,

$$P_{i,t} = \frac{W_{i,t}^{1-\alpha_i} R_{i,t}^{\alpha_i}}{\alpha_i^{\alpha_i} (1-\alpha_i)^{1-\alpha_i} A_{i,t}}, \quad (2)$$

where $R_{i,t}$ is the rental rate of capital and $W_{i,t}$ is the wage rate in sector i . Equation (2) implies that

$$\frac{(P_{c,t}/P_{g,t})}{(P_{c,t}/P_{g,t})} = \underbrace{\alpha_c \frac{\dot{R}_{c,t}}{R_{c,t}} - \alpha_g \frac{\dot{R}_{g,t}}{R_{g,t}} + (1-\alpha_c) \frac{\dot{W}_{c,t}}{W_{c,t}} - (1-\alpha_g) \frac{\dot{W}_{g,t}}{W_{g,t}}}_{(a)} + \underbrace{\frac{(A_{g,t}/A_{c,t})}{(A_{g,t}/A_{c,t})}}_{(b)}. \quad (3)$$

Equation (3) allows us to decompose the growth in the relative price of construction into two components: one (a) that depends on the growth in the price of capital and labor services in the two sectors weighted by the intensity of capital and labor services in production, determined by α_c and α_g ; and the second (b) that depends on the TFP growth differential between the two sectors. By using (3) it is possible to separate the increase in the relative price of construction due to market conditions (changes in the prices of capital and labor) from that due to different TFP growth in the two sectors.

4 Results

If the Cobb-Douglas is a good approximation of the production technology, the price of output measured in the data should be close to the theoretical price given by (2), and (3) can be used to decompose the relative price of construction. To test whether the Cobb-Douglas assumption is supported by the data we first compute TFP $A_{i,t}$ in construction and in the general economy using data for $Y_{i,t}$, $K_{i,t}$, $L_{i,t}$ and (1). Data are from the EU KLEMS Database.⁴ Next, by taking logarithms of (2) we obtain

$$\log(P_{i,t}) = \beta_i + \beta_{i,r} \log(R_{i,t}) + \beta_{i,w} \log(W_{i,t}) + \beta_{i,a} \log(A_{i,t}), \quad (4)$$

where $\beta_i = -\log[\alpha_i^{\alpha_i} (1-\alpha_i)^{1-\alpha_i}]$, $\beta_{i,r} = \alpha_i$, $\beta_{i,w} = 1-\alpha_i$, and $\beta_{i,a} = -1$. Equation (4) can be estimated by using data on $P_{i,t}$, $W_{i,t}$, $R_{i,t}$ and the series of $A_{i,t}$. If the estimated coefficients are statistically significant and close to their theoretical counterparts, then the Cobb-Douglas function represents a good approximation of the production technology. This is true because series $Y_{i,t}$, $K_{i,t}$, $L_{i,t}$, $P_{i,t}$, $W_{i,t}$, $R_{i,t}$ in the EU KLEMS dataset are not constructed subject to the Cobb-Douglas assumption.

Table 1 reports the results of estimates of the unrestricted regressions based on (4) for both construction and the general economy.⁵ All estimated coefficients are close to their theoretical values and statistically significant.⁶ We also run an F -test for constant returns to scale in

⁴See the appendix for details.

⁵Equation (2) implies a stable relationship among the variables $P_{i,t}$, $W_{i,t}$, $R_{i,t}$, and $A_{i,t}$. This implies that the corresponding time series in the data should be cointegrated. Although we do not perform a complete cointegration analysis, we test the stationarity of the residual series of each regression using the Augmented Dickey Fuller test. The residual series are stationary in each regression.

⁶We also run the regressions by imposing the restrictions $\beta_{i,r} + \beta_{i,w} = 1$, and $\beta_{i,a} = -1$. The estimated coefficients are very close to those obtained in the unrestricted regression.

production and find that the null hypothesis cannot be rejected at 1% significance level in all estimations apart from the German general economy. Figure 2 reports the relative price of construction measured in the data (solid blue line) and the theoretical one (circle blue line) constructed using EU KLEMS data and the right hand side of (2). The two series almost perfectly overlap in the graph for all countries.

Finally, we use (3) to decompose the growth in the relative price of construction. Results appear in table 2.⁷ For each country, the first three rows report the average yearly growth rate of the relative price P_C/P_G , of relative TFP A_G/A_C and of relative rentals $(R_C^{\alpha_C} W_C^{1-\alpha_C})/(R_G^{\alpha_G} W_G^{1-\alpha_G})$ while the fourth and the fifth rows report the contribution of relative TFP and relative rentals to the growth of P_C/P_G .⁸

In the U.S., 95% of the increase in the relative price of construction during the 1980-2007 period is explained by the increase in relative TFP. In particular, the acceleration of TFP growth in the general economy occurred in the nineties is responsible for the steep increase in relative TFP measured in the last part of the sample. In the U.K. instead, changes in relative TFP contribute negatively to the relative price of construction, which increased due to the rise in relative rentals. The case of Germany is similar to the U.S. Relative TFP growth is equal to 125% of the growth in the relative price of construction. Finally, in Spain, relative TFP is not responsible for the increase in the relative price of construction during the 1980-2007 period. To conclude, figure 2 reports relative TFP and relative rentals in all countries.

5 Conclusions

We have shown that technological differences between the general economy and the construction sector can account for the evolution of housing prices in the U.S. In the U.K. and Spain, instead, the evolution of construction prices and technological factors accounts for a small part of the surge in housing prices in the last decade. We conclude that, although the timing of the steep increase in housing prices is similar in all countries, the driving forces of this surge are different across countries.

⁷We perform the decomposition experiment for the period in which data are available for the four countries, 1980-2007.

⁸The sum of contributions might not sum to 100% due to large growth rates.

are average annual growth rates. All numbers are in percentages.

6 Data appendix

The EU KLEMS database, November 2009, provides indices of $Y_{i,t}$, $K_{i,t}$, $L_{i,t}$, $P_{i,t}$, $W_{i,t}$, $R_{i,t}$ for the construction sector and the general economy for the U.S., the U.K., Germany and Spain. Data coverage is 1970-2007 for the U.K. and Germany, 1977-2007 for the U.S. and 1980-2007 for Spain. Sources of the Housing Price Index are the Case-Shiller for the U.S. (available since 1987), the Department for Communities and Local Government for the U.K. (available since 1969), Deutsche Bundesbank for Germany (available since 1995) and Ministerio de Vivienda for Spain (available since 1995). To construct figure 1 we use data on housing prices and construction prices from 1987 (which is the first year the Case-Shiller index is available) for the U.S. and the U.K.⁹ For Germany and Spain, the first year for which both series are available is 1995. To obtain results in table 1 and to construct figure 2 we use, for each country, the maximum time span covered in the EU KLEMS database. Finally, in the decomposition experiment in table 2, we use the longest period for which data are available for the four countries, which is 1980-2007.

⁹In figure 1, we report data from 1987 for comparison reasons. Notwithstanding, for the U.K. it is possible to construct the same figure starting in 1969. This figure confirms that the major divergence between the housing and the construction price occurs after 1995.

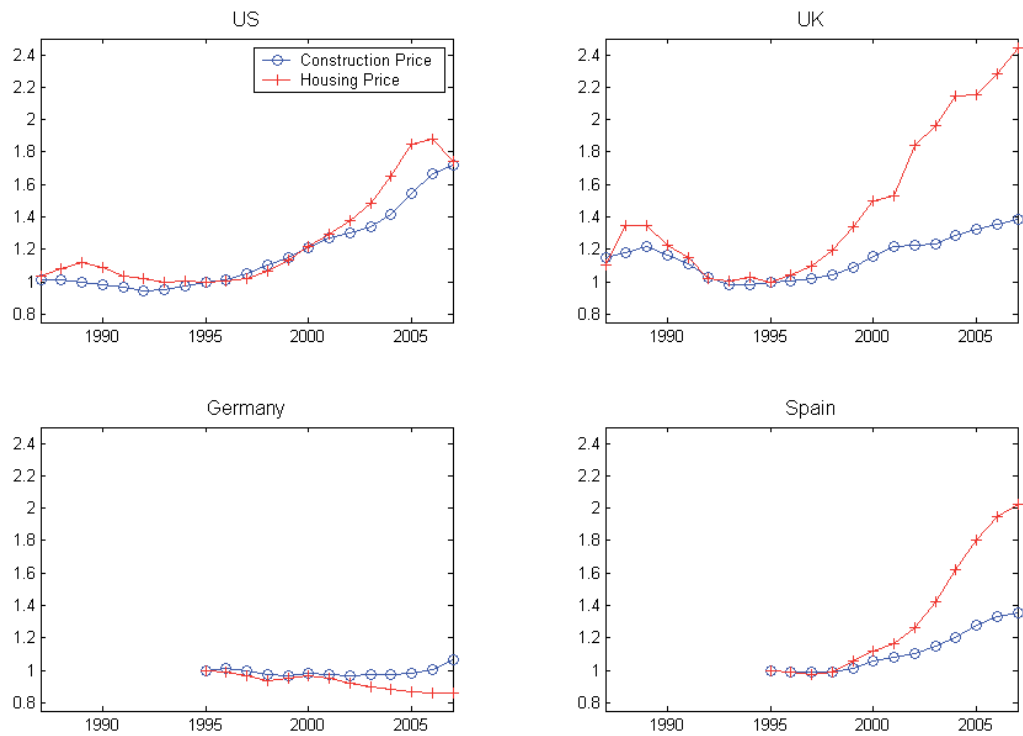

Figure 1: Price of Construction and Price index of Housing for the US, the UK, Germany and Spain. Both indices are divided by the GDP deflator and then normalized to one in 1995. Sources of the Housing Price index are the Case-Shiller for the US, the Department for Communities and Local Government for the UK, Deutsche Bundesbank for Germany and Ministerio de Vivienda for Spain.

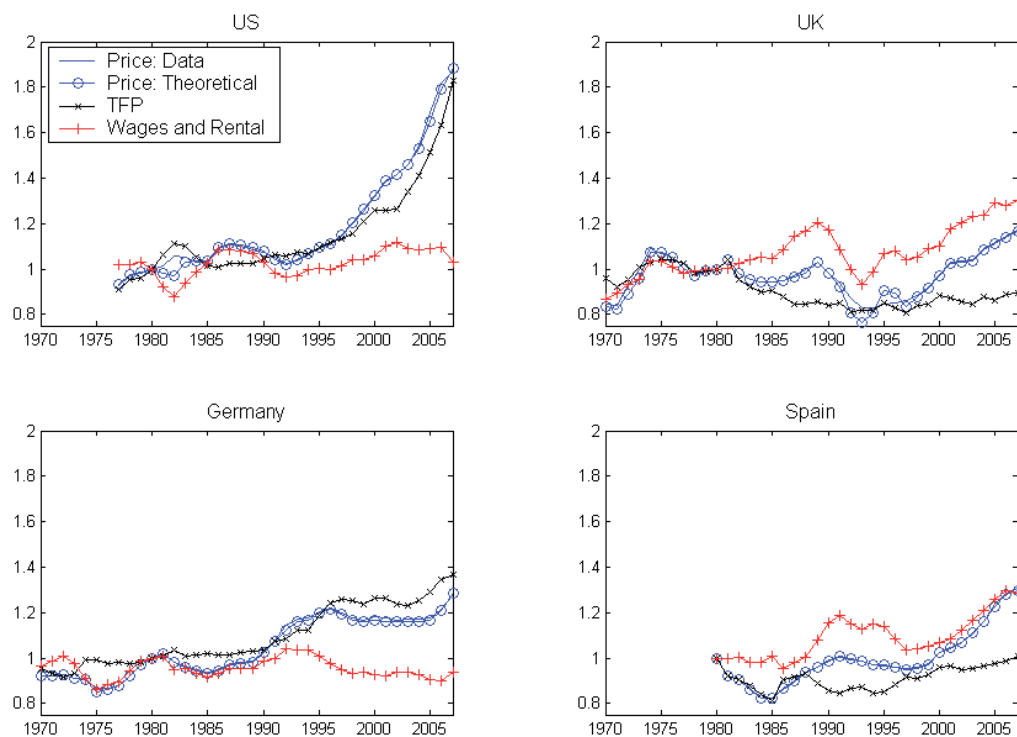

Figure 2: Relative Price of Construction P_C/P_G , Relative TFP A_G/A_C , and Relative Rentals $(R_C^{\alpha_C} W_C^{1-\alpha_C})/(R_G^{\alpha_G} W_G^{1-\alpha_G})$ for the US, the UK, Germany and Spain (1980=1 for all series).
